Pond Delivery Directions (if ordering 10-12" Rainbow Trout): _____

Frequently Asked Questions

Rainbow Trout can tolerate warmer water (55-65°F is optimal) and tend to be somewhat hardier. The rainbow trout is gamier than the brook trout, often leaping from the water to strike a fly and is also excellent eating. Rainbows can survive in stagnant water, have a longer life span and grow faster than brook trout, and can be handled for catch and release fishing.

Brook Trout are native to eastern North America and require a year-round supply of cold, oxygenated water (45-60°F is optimal). The brook trout is generally considered a favorite game fish with its beauty, easy catch-ability, and unrivaled table appeal combining to make it the highly reputable fish that it is.

Generally, it is okay to **mix different species of trout or trout of different sizes**. In some situations, competition, limited feed, and cannibalism can destroy the weaker and/or smaller trout. Trout will eat other trout half their size or less. However, a healthy pond with plenty of insects and plant life will minimize any incompatibility. **Purchasing feed** is generally only for fun. Trout will rise when you throw a handful of feed out and are fun to watch, but their best diet is native insects and plants.

How many trout would be suitable for a pond? Pond conditions dictate numbers and species of trout to stock. The average one-acre pond with a depth of eight feet that stays full all summer with fresh water can generally support 300 trout. Any of several variables may advocate stocking fewer trout, the most important being a dropping water level during the hot, summer months. The warmer the water, the lower the dissolved oxygen content, so it is important not to overstock a pond if the water level tends to drop during late summer.

More information about ponds can be found on websites for the **VT Fish and Wildlife Department**: Wildlife Habitat Management - A Landowner's Guide and **VTDEC Lakes and Ponds Program**: Private Ponds.
